# Experiment No. 10

**Title**

Hosting Website Using Git and GitHub Pages

**Aim**

To deploy and host a static website using Git and GitHub Pages for public accessibility and version control integration.

**Software Required**

- Git
- GitHub account
- Text Editor (VS Code / Notepad)
- Web Browser (Chrome / Firefox)

**Theory**

Git is a distributed version control system used to track changes in source code and manage different versions of a project. It allows developers to efficiently handle updates, collaborate, and maintain project history.

GitHub is a cloud-based platform that hosts Git repositories and provides tools for version control, collaboration, and deployment. One of its important features is **GitHub Pages**, which allows users to host static websites directly from a repository.

A static website consists of HTML, CSS, and JavaScript files that do not require server-side processing. GitHub Pages publishes these files as a live website accessible through a public URL.

By using Git commands, users can upload their website files to GitHub, manage updates, and redeploy changes easily. This makes GitHub Pages a simple and effective solution for hosting static websites.

**Procedure (Detailed Steps)**

**Step 1: Install Git**

Download and install Git on your system.
Verify installation using:

```
git --version
```

**Step 2: Create Project Folder**

Create a folder (e.g., my-website) and add your website files:

- index.html
- style.css
- script.js

**Step 3: Open Terminal**

Open Command Prompt or Git Bash inside the project folder.

**Step 4: Initialize Git Repository**

```
git init
```

This initializes a new Git repository in the folder.

**Step 5: Add Files to Staging Area**

```
git add .
```

This command adds all files to the staging area.

**Step 6: Commit the Files**

```
git commit -m "Initial commit"
```

This saves the current version of the project.

**Step 7: Create GitHub Repository**

Go to GitHub and:

- Click on **New Repository**
- Enter repository name (e.g., my-website)
- Click **Create Repository**

**Step 8: Link Local Repository to GitHub**

```
git remote add origin https://github.com/username/repository-name.git
```

This connects your local project to the GitHub repository.

**Step 9: Push Code to GitHub**

```
git branch -M main
git push -u origin main
```

This uploads your files to GitHub.

**Step 10: Enable GitHub Pages**

- Go to your repository on GitHub
- Click **Settings → Pages**
- Under **Source**:
    - Select **main branch**
    - Select **/root folder**
- Click **Save**

**Step 11: Access Hosted Website**

After deployment, open:

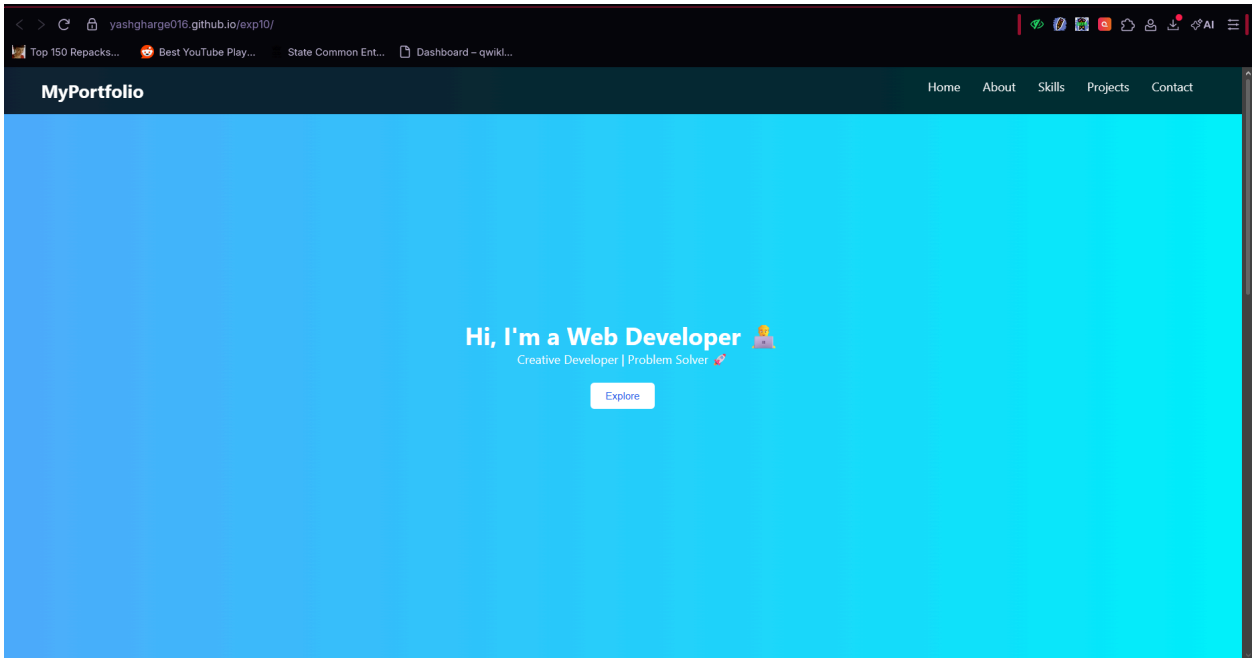
https://username.github.io/repository-name/

**Step 12: Update Website**

Whenever changes are made, use:

```
git add .
git commit -m "Updated website"
git push
```

The website will automatically update.



**Student Task:**

**1)Upload All Experiments to GitHub Using Git Commands**

Upload all completed experiments to a single GitHub repository using Git commands and organize them into separate folders.

**Steps (Using Git Commands)**

1. **Create a main folder for all experiments:**

web-programming-lab/

2. **Inside the folder, create subfolders:**

exp1/

exp2/

exp3/

...

exp10/

3. **Open terminal inside the main folder.**

**Initialize Git Repository**

git init

**Add All Files**

git add .

**Commit the Files**

git commit -m "Added all experiments"

**Connect to GitHub Repository**

git remote add origin https://github.com/username/web-programming-lab.git

**Push to GitHub**

git branch -M main

git push -u origin main

**Update Repository**

git add .

git commit -m "Updated experiments"

git push

```
Yash Gharge@LAPTOP-OQ7E0PCI MINGW64 ~/Desktop/wp experiments (main)
$ git push -u origin main
